Publishing House: O.J. Matematika i Tekhnika, S.G. Karpovich.

REMARKS: This collection of articles is intended for technical personnel interested  
in recent studies and developments of vacuum steelmaking practice and equipment.

CONTENTS: The book contains information on steel-making in vacuum induction furnaces,  
vacuum arc furnaces, reduction processes in vacuum, and degassing of  
steel and alloys. The functioning of apparatus and equipment, especially  
vacuum furnaces and vacuum booster pumps is also analyzed. Personnel are  
invited to compare the contents of the articles and will appear in the table  
of Contents. Three articles have been translated from English. Some of the  
articles are reprinted from "Soviet Metallurgy".

TITLE: A metal mercury vapor unit with a maximal vacuum of  $4 \times 10^{-12}$  mm Hg

SOURCE: Pribory i tekhnika eksperimenta, no. 5, 1965, 177-182

II, 44,55

TOPIC TAGS: ultrahigh vacuum, vacuum ejector pump, high vacuum pump, corrosion,  
corrosion inhibitor, protective coating

ABSTRACT: The present article describes an oil-less, ultrahigh mercury vacuum pumping unit consisting of an N-5SP, 500-liter high-vacuum pump connected to a DRN-50 50-liter auxiliary mercury pump. Results of extensive tests of the unit showed that the maximal vacuum depends by the leakage of hydrogen due to the corrosion of the thin-walled bellows at the outlet of the nitrogen tubing leading from the nitrogen traps. A prevention of this corrosion by the PK-18 anticorrosion silicon-organic enamel coating improved the maximal vacuum of the unit from  $10^{-10}$  to  $10^{-12}$  mm Hg.

The unit's capacity is 85–90 liter/sec in the  $10^{-3}$  to  $10^{-8}$  mm Hg region and 1400 liter/sec in the  $(2-5) \times 10^{-11}$  mm Hg domain. The sharp increase of the action in the ultrahigh vacuum region is due to gas sorbtion on the cold nitrogen trap surface.

Author notes the useful participation of V. I. Gagarin in the experimental part of the investigation. Orig. art. has: 6 figures. 44,55

Samarin, A. M., ed., Corresponding Member, Academy of Sciences USSR.  
Vakuumnaya metallurgiya (Vacuum Metallurgy). Moscow, Metallurgizdat,  
1962. 515 p. Errata slip inserted. 3200 copies printed.

Ed. of Publishing House: V. I. Ptitsyna; Tech. Ed.: L. V. Dobuzhin-  
skaya.

PURPOSE: This book is intended for engineering personnel of metal-  
lurgical and machine-building plants, scientific research workers  
and teachers, and aspirants and students at schools of higher  
technical education.

COVERAGE: Thermodynamic fundamentals of vacuum application in various  
metallurgical processes and problems of melting in vacuum induction  
and arc furnaces are discussed. Procedures of casting large ingots  
and vacuum degassing of steel in ladles are described, along with  
designs of metallurgical vacuum equipment. Problems connected with  
the use of mechanical and steam-ejector vacuum pumps, and with the

AUTHOR: Tseytlin, A. B.

TITLE: The prospects of the application of steam jet ejectors in metallurgy

PERIODICAL: 'Stal', no. 4, 1963, 374 - 377

TEXT: Principles, constructional and operational features of ejector-type pumps used in the vacuum treatment of steel in the ladle or during pouring are described. One of the advantages of such pumps is that a vacuum as low as 0.5 - 1 mm Hg can be produced as against 8 - 3 mm Hg residual pressures with conventional pumps. The steam jet ejectors force out steam at a pressure of 6 - 10 atmospheres and at supersonic speeds. In some types the equipment is provided with condensers. Pressures of  $10^{-1}$  -  $10^{-2}$  mm Hg can be obtained in multi-stage pumps without a condenser in the first stage in which, however, the steam consumption increases considerably. The ejectors can operate in dusty atmosphere without need for filters; they have no rotating parts and may be mounted indoors as well as outdoors. A 5-stage steam jet ejector (type H3B-100x1/NEV-100x1) designed for the zavod "Dneprospetsstal" ("Dneprospetsstal" Plant) has a ca-

The prospects of the application of...

S/133/63/000/004/010/011  
A054/A126

pacity of 100 kg/h at 1 mm Hg, it is supplied with barometric condensers after the 2nd, 3rd and 4th stage; the technical data of this equipment are: rate of operation: 16,500 l/sec, weight: 9 tons, water consumption (at 28°C): 180 m<sup>3</sup>/h, steam consumption (at 15 atm): 2,200 kg/h. In correlation with the amount of steel to be vacuum treated at 0.5 mm Hg the following data should be considered:

Steel charge (ton)	10	25	50	120
Capacity (kg/h)	50	100	200	400

To increase the rate of which the vacuum is produced, a booster ejector is sometimes used, decreasing the pressure from 760 to 100 mm Hg in 1 - 2 min. The application of steam jet ejectors to producing vacuum is economical, as it shortens the melting time and because it is possible to attain a much lower vacuum in the ladle or the electric furnace than with the conventional pumps, which improves the metal quality at low production costs and investments. There are 6 figures.

AUTHOR: Isayev, I.

TYPE: Integral transform method for the biharmonic problem on the half plane

JOURNAL: ANGOL. INVESTIG. APL. MATEM.

TOPIC TAGS: Green function, eigenfunction, differential equation, elasticity

ABSTRACT: The solution of certain biharmonic and related problems on a half plane or half space (often encountered in elasticity) leads to differential equations containing an operator of the type

$$Lw = \frac{\partial^2}{\partial r^2} w + \frac{1}{r} \frac{\partial}{\partial r} w - \lambda^2 w$$

The author constructs certain integral transformations (and their inverses) whose kernels are eigenfunctions of the self-adjoint operator generated by (1). Application is made to a dynamic problem for a semi-infinite elastic plate bounded by a free edge. Only antiplane waves are considered.

TITLE: The method of paired integral equations and paired series and its application to problems of mechanics

SOURCE: Prikladnaya matematika i mehanika, v. 30, no. 2, 1966, 259-270

TOPIC TAGS: integral equation, Fredholm equation, mechanics, series, orthogonal function, BOUNDARY VALUE PROBLEM, ELASTICITY

ABSTRACT: The characteristics of paired integral equations and paired series of the generalized type are investigated. These equations occur in elasticity theory and hydrodynamics as boundary value problems with movable boundaries. The paired series are represented in the symmetric form

$$\int_{-\infty}^{\infty} \rho(\xi) f(\xi) u(\xi, \eta) d\tau(\xi) = g_1(\eta) \quad (a < \eta < c)$$

$$\int_{-\infty}^{\infty} \rho^{-1}(\xi) f(\xi) u(\xi, \eta) d\tau(\xi) = g_2(\eta) \quad (c < \eta < b),$$

and it is assumed that the functions  $\rho(\xi)u(\xi, \eta)$  and  $\rho^{-1}(\xi)u(\xi, \eta)$  are orthogonal. This

Card 1/2

L 30376-66

ACC NR: AP6012545

leads to a linear integral equation of the Fredholm type of the second kind for all  $x$   
with the continuous symmetric kernel,

$$\Psi(\eta, x) + \int_{-\infty}^{\infty} K(x, \eta_1) \Psi(\eta, \eta_1) d\sigma(\eta_1) + K(x; \eta) = 0,$$

The same situation is shown to be true for the paired integral equations

$$\int_{-\infty}^{\infty} p(\xi) [f_1(\xi) + \alpha_1 f_2(\xi)] u(\xi, \eta) d\tau(\xi) = g_1(\eta) \quad (\alpha < \eta < c)$$

$$\int_{-\infty}^{\infty} p(\xi) [f_1(\xi) + \beta_1 f_2(\xi)] u(\xi, \eta) d\tau(\xi) = g_2(\eta)$$

$$\int_{-\infty}^{\infty} p^{-1}(\xi) [f_1(\xi) + \alpha_2 f_2(\xi)] u(\xi, \eta) d\tau(\xi) = g_3(\eta) \quad (c < \eta < b)$$

$$\int_{-\infty}^{\infty} p^{-1}(\xi) [f_1(\xi) + \beta_2 f_2(\xi)] u(\xi, \eta) d\tau(\xi) = g_4(\eta).$$

The results are applied to the plane contact problem in the theory of elasticity for  
the case of an infinite wedge (with polar coordinates) whose tip is pressed in a  
symmetric rigid press without friction. Orig. art. has: 43 equations.

TEXT: The differential equation for the oscillations of an infinite beam resting on a base with two elastic characteristics and, in presence of a length strain, suffering from the effect of a concentrated rectangular impulse, is

$$\frac{\partial^4 y}{\partial x^4} + \frac{1}{a^2} \frac{\partial^2 y}{\partial t^2} + \frac{1}{b^2} y - \frac{1}{c^2} \frac{\partial^2 y}{\partial x^2} = 0,$$

(a, b, c are constants). The author obtains the solution of this equation in the integral form. For the bending and the bending moment in the dangerous cross section there are given expressions in the form of rapidly converging power series. Graphical representations of the maximal values of the bending and of the bending moment are given

TITLE: Effect of titanium on the physical properties of iron-nickel alloys

SOURCE: IVUZ. Chernaya metallurgiya, no. 11, 1966, 105-109

TOPIC TAGS: iron nickel alloy, titanium, metal physical property, magnetic property, Curie point, Young modulus

ABSTRACT: Anomalies of physical properties in binary invars correspond to the region of concentrations adjoining the boundary of irreversible  $\gamma - \beta$  transformation. It has been shown (S. I. Doroshek. FMM, 1964, t. 17, vyp. 14, s. 638) that in certain cases a relationship exists between the effect of alloy elements on the stability of austenite and the position of the anomalies. In this connection, the authors investigate the variation in the concentration dependencies of a number of the physical characteristics of invars under the influence of titanium, which is widely employed as a hardening additive in alloys with special elastic properties. Since under conditions of dispersion hardening the influence of titanium on such anomalies

is largely determined by the change in the composition of the solid solution with segregation or dissolution of the excess intermetallic compound, single-phase Fe-Ni-Ti alloys (30-46 wt. % Ni; 0.6, 2.2 and 4% Ti plus 0.02-0.05% each of C, Mn, Si, Al, Cr, Co, P, S, with Fe as the remainder) in deformed and recrystallized state were investigated. Measurements of physical properties (Young's modulus, temperature variation, Curie point) were performed on specimens of 5 mm diameter. The lattice parameter of the  $\gamma$ -solid solution was measured by the ionization method on recording the line (311); the presence of the  $\alpha$ -phase was fixed according to the line (211). Findings: the Curie point falls with increasing content of Ti (Fig. 1) and hence

Card 3/4

ACC NR: AP6036404

Fe-Ni-Ti alloys must have a higher Ni content in order to display the same ferromagnetic properties as binary invars. Ti weakens the elastic anomaly associated with strictional changes in the dimensions of ferromagnetics at temperatures below the Curie point. Thus an increase in Ti content leads to an appreciable rightward shift of Young's modulus E and of the maximum of the thermoelastic coefficient  $\gamma$  in recrystallized state (Fig. 2). Since the addition of Ti reduces the Curie point and magnetization saturation, it also must reduce the linear magnetostriction (proportional to the square of magnetization); this apparently accounts for the partial elimination of elastic anomaly under the influence of Ti; this also accounts for the anomaly of the lattice parameter. TOPIC TAGS: iron alloy, nickel containing alloy, stress relaxation, relaxation stability, alloy steel/Nispen\*

ABSTRACT: The requirements of modern instruments have increased the need for certain parts made of elastic and sensitive alloys. Among these alloys are Fe-Ni base alloys with chromium, molybdenum, titanium and aluminum. Nispen or N41Kh7, (Ni-41%, Cr-17%, Ti-10%, Mo-7%, Al-1%, C-0.62%), has a minimum temperature coefficient of modulus of elasticity at  $-196^{\circ}\text{C}$  and good mechanical properties at  $-196^{\circ}\text{C}$ . It is also possible to obtain results in a minimum weight instrument part by using a new type of material consisting of Ni-Cr-Al-Mo with alloy N36KHTYuM (Ni-36%, Cr-16%, Al-10%, Mo-7%, C-0.4%).

high strength and elastic properties. It is widely used for bellows, membranes and high strength kinds of springs. The required combination of physical and elastic properties of the material depends on the temperature for which it is used and the service conditions.

The present investigation was conducted to determine the effect of relaxation stress and relaxation time on the mechanical properties of nitrided steel. The samples were cut from a 10 mm thick plate of 42CrMoV4 steel. The surface of the plate was polished and then nitrided at 500°C for 12 hours. The nitrided thickness was determined as 0.15 mm. After nitriding the plate was quenched in oil and then tempered at 200°C for 1 hour. The samples were cut from the center of the plate and were subjected to extension testing. The tests showed that the decrease in the value of temperatures is determined not only by strain rate but also by various structures during testing, in other words by a metastable structure. It may be considered that the decreased stress in cold worked and low tempered bands is to a great extent due to structural transformations caused by rest and aging during high temperature tests. The tests also indicated that the variation of relaxation stability during

Card 2/3

L 15002-65

ACCESSION NR: AT4048139

tempering of the hardened material is very closely connected with the rest processes which increase the degree of structural stability and the yield point. It is known that one of the ways of improving the relaxation stability at high temperatures is the addition of an alloying element. It was therefore suggested that the N36KhTYuM alloy might have an alloying element. Tests showed that this is true, except for the ultimate strength of the material. Tests also showed that the yield stress  $\sigma_y$  was also determined by the heat treatment conditions.

The following table gives the results of tests of the relaxation stability of steels containing high relaxation resistance elements. The table shows the upper limit of relaxation stability. On the basis of these tests, it is considered that the upper limit of working temperatures for steel is 200°C for N41KhT - 300°C for N36KhTYuM - 360°C (Table K-1 of Yu. S. Pecherskaya's publications). Design calculations should be oriented toward the design of structures at temperatures up to 200°C. The minimum temperature sufficient to cause softening of the material is 300°C for N41KhT and 360°C for N36KhTYuM. The modulus of elasticity up to 400°C (Table 4) is given in Figures 1 and 2.

ACCESSION NR: AR4041621

in melts of salts at 300 - 360° for 1 hour, after which mechanical properties on extension and bend, hardness, Curie point and saturation magnetization were measured. Tests on relaxation of stresses were conducted at 300 - 500° by means of heating the tape in rings with initial stress not exceeding  $\sigma_{cr}$ . Maximums of hardness, %, and  $\sigma_{cr}$ , of a dispersion strengthened alloy N41KHT after tempering, at 575 - 600°, where almost complete separation of work hardening phase occurs, the same temperatures correspond to maximum of curves of Curie points and saturation magnetization. Maximum relaxation stability for alloys with 2.26 Ti and 1.17 Mo is observed at 500° (at 575° for dispersion (Mo - 1.25%), whereas  $\sigma_{cr}$  is reserved at 575°. Hardening of dispersion strengthened to highest  $\sigma_{cr}$  in alloy N41KHT is connected with formation of a new phase of intermetallics with  $M_23C_6$  and  $M_2C$ . Relaxation stability of dispersion strengthened alloy N41KHT reached significantly earlier than in dispersion strengthened alloy N36KHT. Increase of relaxation stability during tempering of hardened alloy N41KHT is connected with course of processes of rest, increasing the degree of stability of structure and  $\sigma_{cr}$ . Hardness,  $\sigma_{cr}$  and relaxation stability of alloy N36KHTuM, differing from alloy N41KHT by increased content of Cr and absence of Mo, turns out to be also higher. Addition of Cr and absence of Mo of tempering, ensuring maximum  $\sigma_{cr}$ , addition Cr and absence of Mo of tempering, ensuring maximum work hardening, and the presence of processes of dispersion hardening.

Card 2/3

L 12969-65  
ACCESSION NR: AR4041621

to 600 - 650°. Minimum of removed stress during relaxation of stresses for alloy N36KhTYuM is observed at 550 - 600°, and high relaxation stability after tempering at these temperatures is kept to 450 - 500°. Shift of maximum of relaxation stability in the direction of higher temperatures of tempering is connected with difficulty, caused by alloying, of course of processes of rest and formation of stable structure, combining them with separation of work hardening phase during dispersion hardening. Increase of temperature of tempering above 600 - 650° leads to sharp lowering of relaxation stability, especially at increased test temperatures. Bibliography: 10 references.

deformation, iron nickel alloy, titanium / ~~Bathistic magnetization saturation meter,~~  
URS-50IM x-ray spectral analyzer

ABSTRACT: Treatment of invars with additional alloy elements is known to markedly influence the effect of plastic deformation on physical properties. In this connection the authors investigated the effect of plastic deformation on the magnetic elastic properties and lattice constant of austenite of Fe-Ni (30-47% Ni) alloys treated with 0.6, 2.2 and 4 wt. % Ti. Alloys of this kind, hardenable by aging following quenching or plastic deformation, are widely used in practice to attain a near-zero thermoelastic coefficient, a low coefficient of thermal expansion,

Card 1/4

UDC: 669.15:539.37

ACC NR: AP7002742

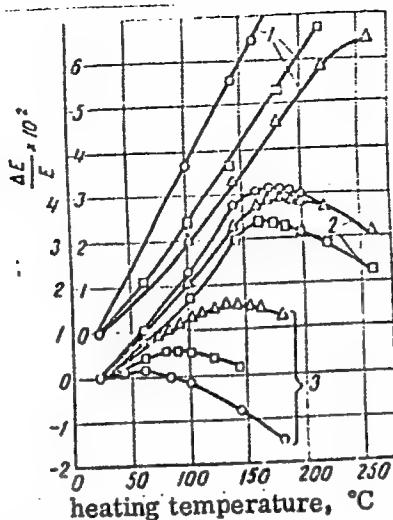

etc. Wire specimens (diameter 5 mm) and strip (0.32x4.0 mm) of the alloy were subjected to plastic deformation by homogenizing (water quenching from 1000°C) and drawing with 22, 52 and 84% reduction in area, after which they were heated to 1000°C for 2 hr and again water-quenched (to prevent the segregation of excess intermetallic compounds). Magnetization saturation  $I_s$  was measured with the aid of a BU-3 ballistic device; electrical resistivity  $\rho$ , by means of a double-bridge circuit; the ferromagnetic Curie point  $\theta_c$ , according to the sloping segment of the magnetization-temperature curve; and Young's modulus E, according to the resonance frequency of transverse oscillations. The lattice constant a of austenite was determined with the aid of Fe  $K_{\alpha}$ -radiation (URS-50IM device) on recording the {311} line. Findings: plastic deformation markedly increases  $I_s$  and  $\theta_c$ , this increase being the greater the higher the Ti content and the lower the Ni content and (for  $\theta_c$ ) the higher the degree of deformation of the alloy are. By contrast,  $\rho$  decreases with increase in Ti content and decrease in Ni content. The marked increase in  $\theta_c$  in low-Ni invars containing 4% Ti and having an 84% deformation causes an anomalous change in the temperature dependence of Young's modulus E (Fig. 1). In the alloy with 0.6% Ti, as in binary invars, plastic deformation reduces the positive slope of the E-temperature curve, whereas in the high-nickel (35% Ni) alloy with 4% Ti (N35T4 alloy) 84% deformation increases  $\theta_c$  by roughly 70°, which increases the positive change in E with temperature and markedly broadens the temperature range of the anomaly. Thus it may be said that plastic

○ - 22% deformation and quenching

deformation enhances the "invarness" of Fe-Ni-Ti alloys. All these changes in physical properties apparently are associated with the concentration anomalies in invars, due to the special nature of these alloys. It appears that the negative exchange interaction between neighboring Fe ions occurring at Ni concentrations of less than 40% leads to the formation and growth of antiferromagnetic regions with an extremely low Neel point and this results in the sharp de-

the steel band is possible with rigorously constant adherence to heat-treatment technology, providing for a minimum quantity of residual austenite before annealing. The presence of residual austenite in the steel disturbs the relationship between the strength and magnetic characteristics when the annealing temperature is changed, thus limiting the sensitivity of the coercitometer.

The use of iron tubes in the lower process of sulfuric acid production. I. R. Arslanov and A. N. Tsvetkov. Akad. Znat. SSR, 11, 408. 13 in German 111 131 (1961). Corrosion of Fe in  $H_2SO_4$  of 57.0%  $H_2O$  is small and comparable to Pb corrosion under the same conditions. Increase of  $Na_2S$  promotes corrosion. By raising the temp. in the presence of  $Na_2S$ , the corrosion does not increase. For use in the production zone, the Fe tubes are more resistant to corrosion than Pb, but in the absorption zone, Pb is more resistant. B. Z. Kamich

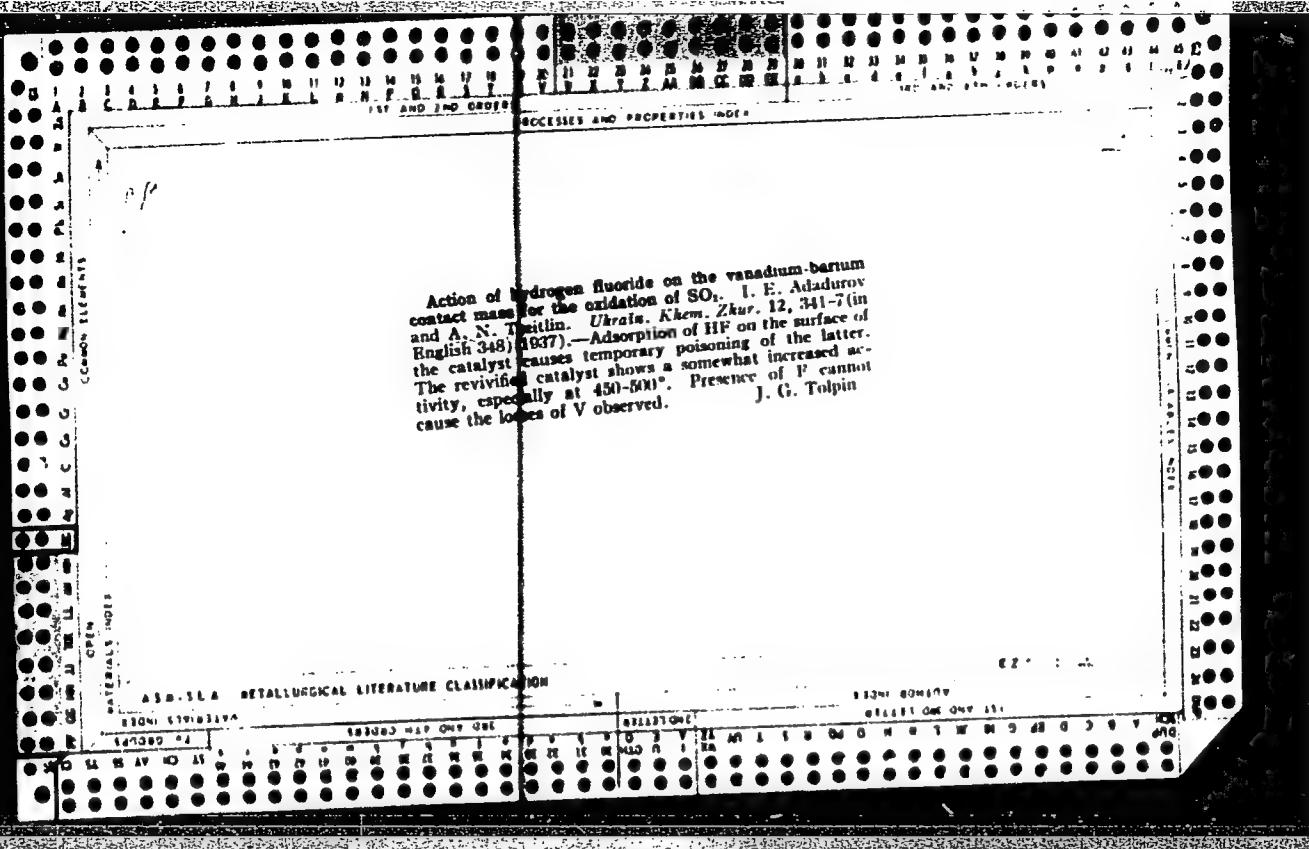

MATERIALS INDEX

ASA-SLA METALLURGICAL LITERATURE CLASSIFICATION

**Use of preliminary catalyst in the manufacture of sulfuric acid.** I. P. Adadurov, A. N. Tschitlin and T. I. Pomicheva, *J. Applied Chem. (U.S.S.R.)* 10, 2017-20 (1937). The use of preliminary catalysts for the  $H_2SO_4$  contact process, to protect Pt against As poisoning, was investigated. The  $CuO-MnO_2$  catalyst is suitable as a preliminary catalyst for the oxidation of sublimed  $As_2S_3$  to nonvolatile  $As_2O_3$  (which is kept on the surface of the preliminary catalyst) with  $O_2$  of the air. Oxide admixts. of  $Co$ ,  $Re$  or  $Si$  increase the activity of the above catalyst. The amt. of oxidized  $As_2O_3$  depends on the vol. velocity, being highest at low vol. velocities. The oxidation of  $As_2O_3$  in the presence of the  $SO_2$ -air mixt. proceeds at a considerable vol. velocity, but the presence of  $Si$ , lowers the life of the catalyst. However, a catalyst activated with  $Si$  preserves its activity for a long time. The surface of a preliminary catalyst is covered with products of the reaction, and, therefore, the process, which takes place on its surface, is periodical. A preliminary catalyst works without lowering its activity if the amt. of  $As_2O_3$  passed through does not exceed 0.1 of its wt. Thereafter the catalyst should be washed with 15% KOH, which completely restores its activity. An increase in the depth of the layer and its sepn. into 2 layers, together with the corresponding change of the vol. velocity, raises the oxidation of  $As_2O_3$  to 100%. The catalyst was stable during a storage for 8 months without protection. *Rxptl. data are given. Eleven references.*

A. A. Postgutov

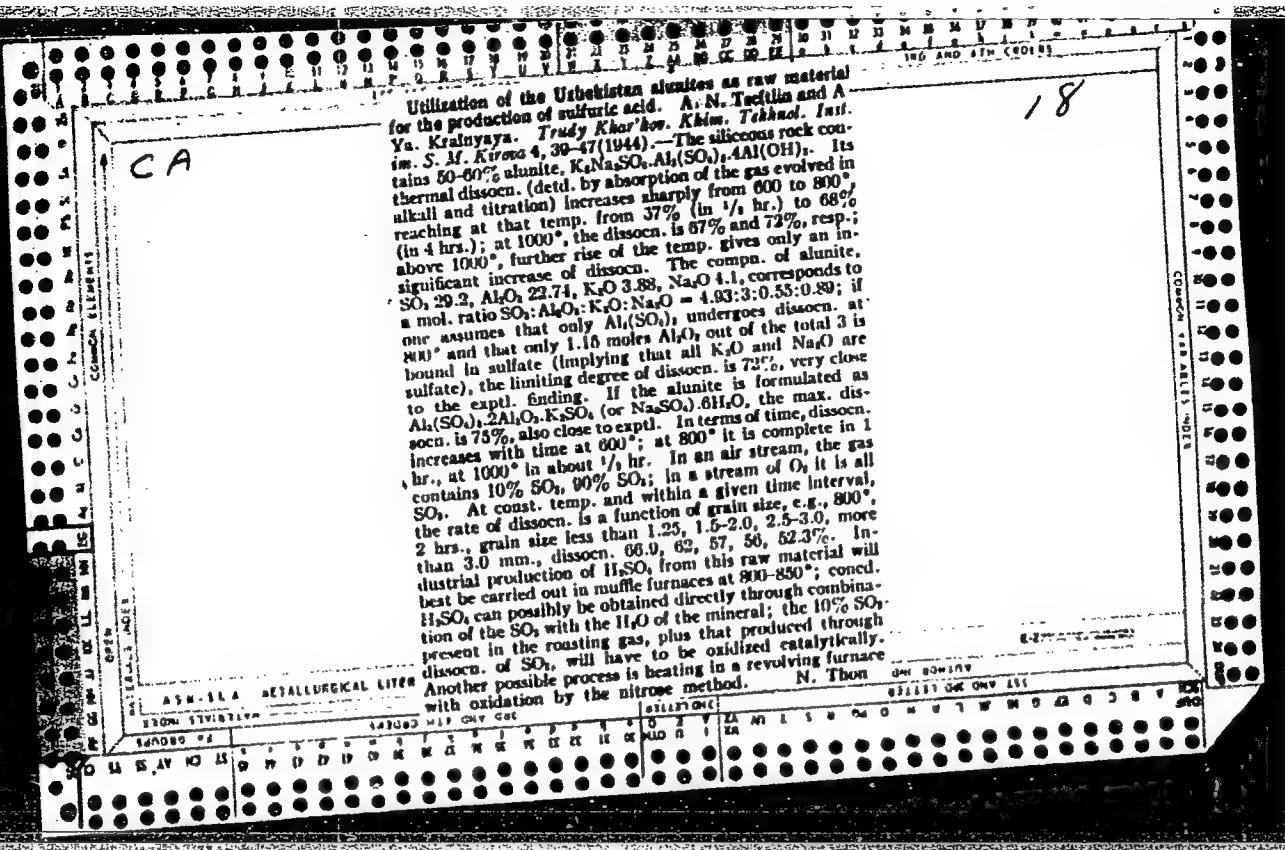

Absorption of sulfur trioxide in sulfuric acid at various temperatures of the gas. A. N. Tselitin and L. M. Pavlovskaya. *Izdat. Akad. Nauk SSSR*, *Zhur. Fiz. Khim.*, *1930*, *N. 1*, Article No. 2, 100-103 (1930).—The degree of SO<sub>3</sub> absorption by surface contact with H<sub>2</sub>SO<sub>4</sub> decreases from 94.0% at 20° to about 48% at 60° and then increases to 91.5% at 150°. By filling the tower with glass beads, the degree of absorption dropped somewhat with increasing temp., but despite the temp. interval of 20-200°, the decrease was only 2.5-4.4%. The expts. indicate that in large-scale plants it is not necessary to cool the gases coming from the contact system, but these, at a temp. of 150-180°, can be absorbed directly. It is only necessary to increase the spray of cold acid in the first absorber.

monitored at higher temps. of combustion, this is 33.2% at 100°, but only 6% at 600°. Likewise, with  $t_1$  increasing from 140 to 180°, the const.  $A'$  decreases 2.5 times or 1000°, but only 1.15 times at 600°; for  $t_1 = 180°$ , the formula is  $\ln A' = 2.48 - 440/T$ , i.e.,  $A'$  is only 440 cal. vs. against 8700 for  $t_1 = 140°$ . Photo of long  $\mu'$  aspirator 1/7 show again an striking anomaly for the line of  $t_1 = 180°$  which does not fit the pattern of the lines  $t_1 = 140, 160$ , and 200°; although the latter tend to converge in the direction of increasing  $(1/T)$ , the  $t_1 = 180°$  line starts below the 200° line (too low  $\mu'$  for the given temps.) and crosses it before reaching its normal position between the 180° and the 200° lines. Also, the fall of  $A'$  with increasing  $t_1$  is slowed down distinctly between  $t_1 = 180°$  and 200°.

With the S being evap'd. in a stream of N ( $\nu = 2$ ), and O<sub>2</sub> (0.5 l/min.) added only before entering the combustion furnace, resulting in 20% O<sub>2</sub> in the fire main, only 2.5% of the S was oxidized at  $t_1 = 200-300$ ; fire-dust increases of the length of combustion, through S's cold reduction of the rate of N and of O<sub>2</sub>, reduced it only to 4-4.5%, as against 9.5% combustion at 80°, 0.75 sec.,  $t_1 = 140, 160, 180, 200$ , 220°, the degrees of combustion were 74.4, 66.3, 60.5, 57.3, and 8.2%.  $\mu' = 1.20, 1.25, 1.12$ , and 0.96, resp. (2) At low- $t_1$  (140°), too much air (500 cm<sup>3</sup>/kg. S) is needed for evapn., as compared with the 10 cm<sup>3</sup>/kg. necessary for the combustion of that amt.; so reduces the amount of air to 10 cm<sup>3</sup>/kg. S, one would have to evap. air 230-240° at which to an instant, combustion is too slow; consequently, the optimum industrial procedure should begin evapn. at a low temp. and complete it at a high temp. (4) In fire combustion of liquid S in air, the mass rate is  $A' = 16.6 \text{ kg./sq.m.-hr.}$  in a tube; in a furnace place in the gas film adjacent to the liquid surface, and is rate is 40. by that of evapn., that the rate of combustion seems to vary relatively little with the temp. In the furnace is due to the fact that the temp. at the phase boundary is actually higher and rather close to the b.p. of S. Increased velocity of the air stream acts both by the increased supply of O<sub>2</sub> and the increase of the rate of desorption of the products. The effect of prolonged combustion is due to gradual rise of the temp. In the same zone.

TITLE: The Utilization of Nitrogen Oxides - the Waste From Some  
Processes

PERIODICAL: Khimicheskaya promyshlennost', 1960, No. 1, pp. 79 - 80

TEXT: The problem of the utilization of nitrogen oxide waste developing during the manufacture of some products of the organic synthesis is dealt with in the paper under review. The development of a simple method for the utilization of nitrogen oxide waste in industry is desirable. The principal reactions which determine the forming of nitric acid from nitrogen oxide are mentioned and equations for the reaction rate are given. The utilization of highly concentrated nitrogen oxides permits the production of 55% nitric acid in accordance with the equation of equilibrium of the second reaction ( $K_p = P_{NO}/P_{NO_2}$ ). The absorption takes place in a bubbling column which represents an absorber of improved type in the

given case. The high nitrogen oxide content in the gas permits also a simplified gas flow through the system, the gas flow being obtained with the aid of a vacuum pump of the type RMK (from acid-resisting alloys). The arrangement is given schematically (Fig.) and its characteristic values are given. The oxygen consumption for a daily production of 55% of  $\text{HNO}_3$  amounts to  $14 \text{ m}^3/\text{h}$  in all; the dimensions of the second cooler are reduced to two sevenths, the weight of the column to one fourth, the number of bottoms to 8, and the consumption of electric power to one fifth. There is 1 figure.

AUTHOR: Safiullin, N. Sh.; Tseytlin, A. N.

TITLE: Absorption of nitric oxides by sulfuric acid

SOURCE: Zhurnal prikladnoy khimii, v. 36, no. 3, 1963, 490-495

TOPIC TAGS: nitric oxides, absorption

ABSTRACT: In the study of the effect of a number of factors on the speed of absorption of nitric oxides in sulfuric acid containing 0.15-0.20% NO<sub>2</sub>, it was found that the absorption of nitric oxides is noticeably increased as the concentration of sulfuric acid is increased to 85%. A further increase in the sulfuric acid concentration does not contribute to the speed of absorption. The increase of linear speed of gas by more than 0.5 m/sec and the density of flow more than 6-7 m<sup>3</sup> / m<sup>2</sup> x hour does not change the speed of absorption of nitric oxides. When the nitration of concentrated sulfuric acid is increased from 0.0 to 4.4% HNO<sub>3</sub>, the speed of absorption of nitric oxides is decreased only by 8%. The temperature of the apparatus shows a considerable effect on the speed of absorption of nitric oxides. The relative speeds of absorption of nitric oxides at the temperatures 18, 40 and 60°C are 1:0.48:0.38 respectively. Original article has: 2 tables, 7 graphs, 2 figures.

TITLE: Service Tests of High-Speed Steel Milling Cutters

PERIODICAL: Mashinostroitel', 1960, No. 11, pp. 27-28

TEXT: The authors report on service tests which were carried out with new high-speed steel grades developed by the Tsentral'nyy nauchno-issledovatel'skiy institut chernoy metallurgii (Central Scientific Research Institute of Ferrous Metallurgy) under the leadership of A. G. Ivanov, Candidate of Technical Sciences.

The tests, effected with profile cutters and end cutters of the new high-speed steel grades P18F2 (R18F2), P24 (R24) P9K10 (R9K10) and P9K5 (R9K5), showed that the efficiency of machining heat-resistant steel could be increased by 2 - 3 times. The R24 high-speed steel grade differs from the R18 grade steel by a higher tungsten content, while the high-speed steel grades R18F2, R9K10 and R9K5 differ from the steel grades R18 and R9 by higher vanadium and cobalt contents, which increases the life and red hardness of the tools. The forging and heat-treatment conditions of high-speed steel tools are given in the following table:

At the beginning the forging blanks are heated up slowly to 750 - 800°C, then heating takes place rapidly. The forged blanks are heated in the furnace up to 730 - 780°C, holding takes place at the same temperatures for 3 - 6 hours, then they are cooled down to room temperature. The blanks are annealed in cases filled with cast iron chips, at temperatures in the range of 840 - 850°C, holding takes place for 3 - 4 hours. Then the furnace with the blanks is cooled down to 730 - 750°C at a rate of 20 - 30°C/hour, holding takes place for 3 - 4 hours and further
